Anyone who reads the project can re not introduced by recent work; the project's ov it as something that must be replaced, and tha depends on whether the same password is use has not been established either way and shoul value is already public, changing the files alon be changed everywhere it is used, and the setu configuration source rather than containing it. cannot honestly claim its credentials are prote
HXC-171	Bug	Queued	Medium	A complete copy of somebody else's web applic it alone accounts for one hundred and thirty-n dependency security warnings, including thre be built or run: the startup configuration poin that folder, and its supporting packages have n two opposite ways at once. Because it is not bu we actually run today, which is why they rank

ATM ID	Type	Status	Severity	Description
HXC-172	Task	Operator-blocked	High	references it, the setup is broken and misleading. The recipe file, all one hundred and thirty-nine was sent to whoever does it. Anyone reading our security report is a distortion, since it currently buries the small number of warnings. The expected outcome is an explicit decision, not to properly maintain and build it, or remove it and replace it with a reference to the upstream hosted service. Before any approval, the decision must be put to the operator. A small companion service we wrote ourselves is not part of the standard deployment, and it carries several supporting packages, two of them rated high. Under the three warnings, these have no mitigating evidence in the unshipped, because it demonstrably ships, and it is not clear whether the affected functionality is ever exercised. It is a place in the whole review where something was overlooked, which makes it far more deserving of attention than the other three is not really an upgrade problem at all: it is not switched off unless explicitly enabled, so updating the protection on would leave the exposure in place. The current deployment running this service benefit. The evidence in the assessment of the three warnings, the two strategies for the protective setting explicitly verified as enabled, the cache and the service rebuilt and confirmed working. The cache that remembers model information is not in the code where its clock was never configured. That falls outside the only way to build the cache always configured, but it is unexercised. On its own that is harmless. The risk is that if someone later edits it: a plausible-looking change that the current time would make every cached entry a failure in the past that the freshness check reads as a failure. Every entry would then be considered expired, and keep serving outdated model information indefinitely. The choice is to either add a small test that pins the failure to a branch entirely and document that there is one, or to reject it. When a caller presents an API key, the server compares it with an ordinary text comparison. That kind of comparison is not one that does not match, so a key sharing the first few characters is more reject than one that differs immediately. An attacker can recover differences across many attempts can recover the key by brute force guessing it outright. Network timing noise makes this attack is low rather than urgent, but it is a genuine weakness. A cheap: use the comparison function designed for this purpose.
HXC-175	Bug	Queued	Low	The cache that remembers model information is not in the code where its clock was never configured. That falls outside the only way to build the cache always configured, but it is unexercised. On its own that is harmless. The risk is that if someone later edits it: a plausible-looking change that the current time would make every cached entry a failure in the past that the freshness check reads as a failure. Every entry would then be considered expired, and keep serving outdated model information indefinitely. The choice is to either add a small test that pins the failure to a branch entirely and document that there is one, or to reject it.

ATM ID	Type	Status	Severity	Description
				amount of time regardless of where the difference was introduced by recent work.
HXC-179	Task	Queued	Medium	The check that decides which websites may open deliberately allows requests that carry no original behaviour, because only browsers send that information and legitimately omit it. It is safe today only because it prevents away anyone without valid credentials. The two things nothing records or enforces that coupling: if someone logs in check while working on something unrelated, the information would become completely ungated. The work here is to add a check that specifically covers the connection upgrade, so the dependency is removed. Three commits in the current release range do not refer to a piece of data that was not added in the past. Those three points gets a build error. The tip of the branch corrected shortly afterwards. This cannot be retracted without rewriting published history, which the project does not want. It is for anyone hunting a regression by stepping through three points that fail to build for a reason unrelated to the three points. They may wrongly conclude the fault lies there. The project is affected points and their shared cause somewhat. The project so the failure is recognised immediately as known and fixed from scratch.
HXC-180	Task	Queued	Low	HXC-160 corrected the 21 stale references to scripts/generate_fixed_summary.sh across the project. It added the CM-SUPERSEDED-GENERATOR-NAMES to the project. The sets were deliberately left untouched and are the same as the Constitution.md still carries 14 references across the project. The universal rules that projects other than HelixCode carry records such as the Phase 5 Go-binary-shim plan. The project is a governance amendment that CONST-049 records. The project configured upstream, then re-cascaded and pushed. The project session that closed HXC-160, and a canon amendment. The project drift than the stale wording, so the canon was corrected. The 45 owned submodules carry cascaded restatement. The project correction applied in the parent repo is deliberate. The project because the fix names a HelixCode-specific mechanism. The project wording into decoupled, project-agnostic submodules. The project them and violate CONST-051(B). The correct session. The project neutral canonical wording that names the work. The project and push it in the constitution submodule per the project. The project fleet and bump pointers. Who benefits: every one.

ATM ID	Type	Status	Severity	Description
				the anchor text, and any agent reading a summary summaries are produced. Acceptance: canon wording, the change is pushed to every constituent are re-cascaded, submodule pointers are bumped SUPERSEDED-GENERATOR-NAMING both pass Every shipped change must carry recorded proof by looking for the change's identifier inside the automatically stamp in whatever the project's were recorded. That stamp is an identifier of evidence file written while the project happened by coincidence, be accepted as that change's proof completely unrelated. This has not yet happened made while the project sat at a position that re available to every recording the shared tooling accept only identifiers deliberately declared as incidental position stamp. This needs care because acceptance from evidence already recorded, so quiet correction. The main handbook that tells contributors and organised lists several folders at the top level when only one is present, and refers to a top-level Anyone following it — a new contributor, or an orientation — will look for things that are not broken or that they have checked out the wrong of the document, which is otherwise the author. The correction is small and purely descriptive: section to match, then keep the two in step as to One of the external projects this codebase depends configuration still refers to it by its previous name hosting service silently forwards requests from forwarding is a courtesy, not a guarantee: it did project under the old name, and it is not honoring dependency. If it stops working, fetching the project name nobody recognises, which is unusually common project's current canonical name so the reference on a redirect continuing to exist. When a running command is cut short because says it was not a timeout. The check that sets the caller's own deadline, which usually has not stopped the command. Investigation showed that either, because the internal signal it would come cancellation and never a timeout, and the time

				mechanism entirely. The effect is that anyone can cause a failure and no indication that a time limit was reached was in the wrong place. A sibling code path that runs correctly by doing it inside the timer's own callout can't copy. When a command is cancelled or times out, the timer is not but anything it started, by signalling the whole group, it works if the command was placed into its own timer. If the sandbox enabled — the normal configuration — the sandbox switched off, the grouping step is skipped. The operating system to signal a group that does not exist, an error is discarded. The result is a cancelled command that is dormant, because the only configuration that could reach it so no shipped path reaches it. It is worth fixing this, but it would appear only in an unusual configuration and is diagnosed later.
HXC-191	Bug	Queued	Low	
HXC-192	Bug	Queued	Low	Output from a running command is read line by line. The line may be. When a line exceeds that limit the command is permanently for that stream, because the buffer is past it. Nothing else takes over the reading. The command is until the operating system's own small buffer fills up and someone to read. So one unusually long line, which is readable output produce quite naturally, can wait for a while is to keep draining and discarding the remainder of the line, abandoning the stream, so the producing command is not
HXC-196	Task	Queued	Medium	The handbook that describes this project's technology is one of its networking libraries. Both parts of the handbook because a security fix required moving off the old one, deliberate; it is the handbook that is now wrong. A new contributor or an automated helper reader will confidently state a version that has not been found. The same document has already been found described in the additional inaccuracy makes the whole document wrong. The recorded version to what is actually in use, and the reason, so nobody later reverts it believing the handbook
HXC-197	Bug	Queued	Low	One test directory contains a duplicate of its own files. The files appear twice in the project at two different times. A renaming exercise that moved a tree while leaving the new one. Nothing reads the nested copy, so the test. Anyone searching the project finds two results, one of which is real, and any tool that scans for duplicate files blocks a useful check from being switched on:

ATM ID	Type	Status	Severity	Description
				duplicates cannot be enabled while this one exists every run. Removing it requires first confirming the nested copy is genuinely the leftover and not the original. A recent change gave one part of the project a new identity. The code could stop claiming the same identity. A corner case problem still exists searches for the old name and the code contains the old one as a prefix — so the check for the name as unfixed even though it is fixed. Anyone re-running the test already done, and might undo the fix believing the test also still describes the old arrangement in three parts of the whole name rather than a fragment, and to be consistent with what the code actually does now.
HXC-199	Bug	Queued	Medium	
				A detector was written to catch a specific kind of error where a worker stuck trying to hand off a result nobody is collecting. It was one particular description of what the worker was doing in the form of the same stall — where the worker was waiting for a handoff rather than a single handoff — and the detector was not demonstrated rather than theorised: a deliberate test case went completely undetected while the detector was running. What it does catch is the historical one, so the guard is still looking at the newer structure while breaking its escape condition. To recognise both descriptions is a small change and the detector is a defect rather than half of it.
HXC-200	Bug	Queued	Low	
				A recent change taught the product to correctly handle the combination of combining them with a port number. It was applied to the address to listen on, but not in the desktop application. The address it connects to from the very same two addresses was the address configured, the server starts up correctly. The unusable address and cannot reach it — a failure condition that is running perfectly. A second instance exists in the analysis service. Neither is newly broken; both were broken in the original change examined, so nothing was made worse. The working cycle that a correct change was applied to the same thing nearby, which is worth treating as a failure due to oversights.
HXC-202	Bug	Queued	Medium	
				Two long-running tests — one exercising heavy load and one exercising leader election among worker nodes — both report failure when the machine is under load. The tests are on their own. Measured: during a full test run both fail about 10 times consecutively, one finishing in roughly a third of the time about a twentieth. Their verdicts are therefore not reliable indicators of whether the product works. This matters most
HXC-204	Bug	Queued	Medium	

ATM ID	Type	Status	Severity	Description
				test run performed before a release is by definition broken. These two will mark a healthy release as broken through. A third test with the same problem will be an inconclusive run report as skipped rather than as failed. The same treatment fits here. Both should wait for a fixed time rather than assuming a fixed time is enough. The newly-fixed health refresh deliberately refreshes the provider over the network, so that a slow or healthy provider can be refreshed. It then re-acquires the lock and only applies its changes if the state has changed underneath it. There is a narrow race condition where, if started again entirely within one probe, the change is not applied. It applies a verdict formed against the previous information. It was briefly reported unhealthy when it is fine, which is a dangerous direction — reporting a stopped probe as healthy. Worth recording that this is cheap to close rather than expensive. The incremented on each state change is invisible to the user, to any published structure. An earlier note describing this was wrong and has been retracted. When a model provider record is created, its entry is shared template by reference rather than copied. It points at the same underlying settings, including the underlying settings. Nothing writes to those settings today, and the settings are not corrupted. No corruption occurs at present — this was very surprising. The record it is that the protection now added to the record manager cannot protect a structure shared with the provider. A legitimate, properly-locked write to a provider record is visible to the manager's view as well, and the locking will lock the record when the record is created removes the hazard. Four compose entries across two end-to-end tests, between the Slack mock and the LLM-provider mock, but the tests fail. Any attempt to build those stacks therefore fails. This is a failure which means the containerised form of these tests is not exercised. This was surfaced while fixing an unrelated issue. The same two services: the fix could be proven at the time against a running container, precisely because the tests were produced. That gap matters beyond these two tests. The process leaves the deployed-artifact layer unproven. In failure the four-layer verification discipline exists. The Dockerfiles, or to remove the build entries if the tests are run containerised, and then to prove the choice.

HXC-207	Bug	Queued	Low	
HXC-208	Bug	Queued	—	
HXC-216	Task	Queued	—	A blanket rule excluding log files from version control. Evidence, because evidence transcripts are written to log files.

ATM ID	Type	Status	Severity	Description
				corrected so this cannot happen again, and the have been recovered and committed. Thirty-five the runs exist only on the machine that produced an evidence folder that appears empty, which never run. Recovering them is not automatic, but seventy-eight megabytes and committing those deserves a deliberate decision rather than a re-keep what genuinely substantiates a closed item ones rather than storing them whole, and recording why, so the gap is visible rather than silent.
