Anyone who reads the project can re not introduced by recent work; the project's ov it as something that must be replaced, and tha depends on whether the same password is use has not been established either way and shoul value is already public, changing the files alon be changed everywhere it is used, and the setu configuration source rather than containing it. cannot honestly claim its credentials are prote
HXC-171	Bug	Queued	Medium	A complete copy of somebody else's web applic it alone accounts for one hundred and thirty-n dependency security warnings, including thre be built or run: the startup configuration poin that folder, and its supporting packages have n two opposite ways at once. Because it is not bu we actually run today, which is why they rank

ATM ID	Type	Status	Severity	Description
				references it, the setup is broken and misleading. The recipe file, all one hundred and thirty-nine was sent to whoever does it. Anyone reading our security report is a distortion, since it currently buries the small number of warnings. The expected outcome is an explicit decision, not to properly maintain and build it, or remove it and replace it with a reference to the upstream hosted service. Before any approval, the decision must be put to the operator. A small companion service we wrote ourselves is not part of the standard deployment, and it carries several supporting packages, two of them rated high. Under the three warnings, these have no mitigating evidence in the code, unshipped, because it demonstrably ships, and it is not clear whether the affected functionality is ever exercised. It has a place in the whole review where something was missing, which makes it far more deserving of attention than the other three is not really an upgrade problem at all: it is not switched off unless explicitly enabled, so updating it without protection on would leave the exposure in place. The current deployment running this service benefit. The evidence in the assessment of the three warnings, the two strategies, the protective setting explicitly verified as enabled, the service and the service rebuilt and confirmed working. The cache that remembers model information is not in the code where its clock was never configured. That falls outside the only way to build the cache always configured, but it is unexercised. On its own that is harmless. The risk is that if someone later edits it: a plausible-looking change that the current time would make every cached entry a failure in the past that the freshness check reads as a failure. Every expiry limit. Every entry would then be considered expired and keep serving outdated model information indefinitely. The choice is to either add a small test that pins the failure to a branch entirely and document that there is one. When a caller presents an API key, the server does a simple ordinary text comparison. That kind of comparison is not one that does not match, so a key sharing the first few characters is more reject than one that differs immediately. An attacker can exploit differences across many attempts can recover the key by guessing it outright. Network timing noise makes this problem is low rather than urgent, but it is a genuine weakness. A cheap: use the comparison function designed for this purpose.

				amount of time regardless of where the difference was introduced by recent work. The check that decides which websites may open deliberately allows requests that carry no original behaviour, because only browsers send that information and legitimately omit it. It is safe today only because it keeps away anyone without valid credentials. The two things are nothing records or enforces that coupling: if someone does a login check while working on something unrelated, the information would become completely ungated. The work here is to add a check that specifically covers the connection upgrade, so the dependency is removed. Three commits in the current release range do not refer to a piece of data that was not added in the first three points gets a build error. The tip of the range corrected shortly afterwards. This cannot be reworked without rewriting published history, which the project does not want to do. It is for anyone hunting a regression by stepping through the three points that fail to build for a reason unrelated to the three points may wrongly conclude the fault lies there. The fix is to affect the affected points and their shared cause somewhat, so the failure is recognised immediately as known and fixed from scratch.
HXC-179	Task	Queued	Medium	
HXC-180	Task	Queued	Low	HXC-160 corrected the 21 stale references to scripts/generate_fixed_summary.sh across the repository. It added the CM-SUPERSEDED-GENERATOR-NAMES to the sets were deliberately left untouched and are to be preserved. Constitution.md still carries 14 references across the repository. universal rules that projects other than HelixCode can't have records such as the Phase 5 Go-binary-shim plan. This is a governance amendment that CONST-049 requires to be configured upstream, then re-cascaded and pushed. The session that closed HXC-160, and a canon amendment to prevent drift than the stale wording, so the canon was updated. 45 owned submodules carry cascaded restatement of the correction applied in the parent repo is deliberate. because the fix names a HelixCode-specific mechanism. The wording into decoupled, project-agnostic submodules. They then violate them and violate CONST-051(B). The correct solution is neutral canonical wording that names the work as a proposal and push it in the constitution submodule per the plan. fleet and bump pointers. Who benefits: every one.
HXC-181	Task	Queued	Medium	

ATM ID	Type	Status	Severity	Description
				the anchor text, and any agent reading a summary summaries are produced. Acceptance: canon wording, the change is pushed to every constituent are re-cascaded, submodule pointers are bumped SUPERSEDED-GENERATOR-NAMING both pass Every shipped change must carry recorded proof by looking for the change's identifier inside the automatically stamp in whatever the project's were recorded. That stamp is an identifier of evidence file written while the project happened by coincidence, be accepted as that change's proof completely unrelated. This has not yet happened made while the project sat at a position that re available to every recording the shared tooling accept only identifiers deliberately declared as incidental position stamp. This needs care because acceptance from evidence already recorded, so quiet correction. The main handbook that tells contributors and organised lists several folders at the top level when only one is present, and refers to a top-level Anyone following it — a new contributor, or an orientation — will look for things that are not broken or that they have checked out the wrong of the document, which is otherwise the author. The correction is small and purely descriptive: section to match, then keep the two in step as to One of the external projects this codebase depends configuration still refers to it by its previous name hosting service silently forwards requests from forwarding is a courtesy, not a guarantee: it did project under the old name, and it is not honoring dependency. If it stops working, fetching the project name nobody recognises, which is unusually common project's current canonical name so the reference on a redirect continuing to exist. When a running command is cut short because says it was not a timeout. The check that sets the caller's own deadline, which usually has not stopped the command. Investigation showed that either, because the internal signal it would come cancellation and never a timeout, and the time

ATM ID	Type	Status	Severity	Description
				mechanism entirely. The effect is that anyone can cause a failure and no indication that a time limit was reached was in the wrong place. A sibling code path that runs correctly by doing it inside the timer's own callout can't copy. When a command is cancelled or times out, the timer is not but anything it started, by signalling the whole group, it works if the command was placed into its own timer. If the sandbox enabled — the normal configuration — the sandbox switched off, the grouping step is skipped. The operating system to signal a group that does not exist, an error is discarded. The result is a cancelled command that is dormant, because the only configuration that could reach it so no shipped path reaches it. It is worth fixing this, but it would appear only in an unusual configuration and is hard to diagnose later.
HXC-191	Bug	Queued	Low	
HXC-192	Bug	Queued	Low	Output from a running command is read line by line. The line may be. When a line exceeds that limit the command is permanently for that stream, because the buffer is full and past it. Nothing else takes over the reading. The command is not until the operating system's own small buffer full, then someone to read. So one unusually long line, which is not readable output produce quite naturally, can wait until the buffer is to keep draining and discarding the remainder, abandoning the stream, so the producing command is not.
HXC-196	Task	Queued	Medium	The handbook that describes this project's technology is one of its networking libraries. Both parts of the handbook are because a security fix required moving off the old handbook, deliberate; it is the handbook that is now wrong. It is a new contributor or an automated helper read the handbook will confidently state a version that has not been found. The same document has already been found described in the handbook, additional inaccuracy makes the whole document wrong. The recorded version to what is actually in use, and the handbook is a reason, so nobody later reverts it believing the handbook is wrong.
HXC-197	Bug	Queued	Low	One test directory contains a duplicate of its own contents. The files appear twice in the project at two different locations. A renaming exercise that moved a tree while leaving the old one the new one. Nothing reads the nested copy, so the handbook anyone searching the project finds two results. The handbook which is real, and any tool that scans for duplicates blocks a useful check from being switched on: the handbook is wrong.

ATM ID	Type	Status	Severity	Description
				duplicates cannot be enabled while this one exists every run. Removing it requires first confirming the nested copy is genuinely the leftover and not the original. A recent change gave one part of the project a new identity. The code could stop claiming the same identity. A corner case problem still exists searches for the old name and the code contains the old one as a prefix — so the check fails as unfixed even though it is fixed. Anyone re-running the test already done, and might undo the fix believing the test also still describes the old arrangement in three parts of the whole name rather than a fragment, and to match what the code actually does now.
HXC-199	Bug	Queued	Medium	
				A detector was written to catch a specific kind of error stuck trying to hand off a result nobody is collecting. It has one particular description of what the worker is doing in the form of the same stall — where the worker was waiting for rather than a single handoff — and the detector failed to demonstrate rather than theorised: a deliberate error went completely undetected while the detector was running. What it does catch is the historical one, so the guard is still looking at the newer structure while breaking its escape condition. To recognise both descriptions is a small change and the detector is a defect rather than half of it.
HXC-200	Bug	Queued	Low	
				A recent change taught the product to correctly handle the combination of combining them with a port number. It was applied to the address to listen on, but not in the desktop application. The address it connects to from the very same two addresses was the address configured, the server starts up correctly. The unusable address and cannot reach it — a failure that the product is running perfectly. A second instance exists in the product analysis service. Neither is newly broken; both were broken in the original change examined, so nothing was made of it. The working cycle that a correct change was applied to the same thing nearby, which is worth treating as a failure of the oversights.
HXC-202	Bug	Queued	Medium	
				Two long-running tests — one exercising heavy load and one exercising leader election among worker nodes — both report failure when the machine is under load. The first is on its own. Measured: during a full test run both fail the same number of times consecutively, one finishing in roughly a third and the other about a twentieth. Their verdicts are therefore not reliable indicators of whether the product works. This matters most
HXC-204	Bug	Queued	Medium	

ATM ID	Type	Status	Severity	Description
				test run performed before a release is by definition broken. These two will mark a healthy release as broken through. A third test with the same problem will mark an inconclusive run report as skipped rather than broken. The same treatment fits here. Both should wait for a test to pass rather than assuming a fixed time is enough. The newly-fixed health refresh deliberately refreshes the provider over the network, so that a slow or hanging refresh will not block. It then re-acquires the lock and only applies its changes if the state has changed underneath it. There is a narrow race where a refresh started again entirely within one probe, the check will be applied, and applies a verdict formed against the previous information. It briefly reported unhealthy when it is fine, which is a dangerous direction — reporting a stopped probe as broken. Worth recording that this is cheap to close rather than expensive. The incremented on each state change is invisible to the user, to any published structure. An earlier note describing this was wrong and has been retracted.
HXC-206	Bug	Queued	Low	
HXC-207	Bug	Queued	Low	When a model provider record is created, its entry is shared template by reference rather than copied. This points at the same underlying settings, including the provider. Nothing writes to those settings today, and the settings are not corrupted. No corruption occurs at present — this was very surprising. The record it is that the protection now added to the provider manager cannot protect a structure shared with the provider. A legitimate, properly-locked write to a provider record will update the manager's view as well, and the locking will lock the record. When the record is created removes the hazard.
HXC-208	Bug	Queued	—	Four compose entries across two end-to-end tests, one in the Slack mock and the LLM-provider mock, both fail. Any attempt to build those stacks therefore fails. This is a failure which means the containerised form of these tests cannot be exercised. This was surfaced while fixing an unrelated issue. The same two services: the fix could be proven at the time by running against a running container, precisely because the fix was produced. That gap matters beyond these two tests. The process leaves the deployed-artifact layer unproven. In the failure the four-layer verification discipline exists. The fix is in Dockerfiles, or to remove the build entries if the tests are run containerised, and then to prove the choice.
HXC-211	Bug	Queued	—	The hang just repaired was one instance of a problem where the same package, each able to park a call forever.

ATM ID	Type	Status	Severity	Description
				permits. Two sit in the synchronous execution sandboxing is switched off or when no timeout through documented usage rather than miscommunication streaming helper and are presently safe only because to rescue them, so any future caller wiring that original defect exactly. A fifth site in the background calling into this code with no timeout and no warning found by sweeping the whole package after the report, which was necessary because the race turned out to live in different files, so a review found nothing.
HXC-213	Bug	Queued	—	A component that tracks the progress of a process protecting its shared status record, and then updates touching the same record in seventy-eight other places fixed elsewhere, and it is not speculative: a corner case was previously detected here by the race detector guarded only the single line the detector happened to be untouched. So the file now reads as though it is locked than having no lock at all, because a reader sees Concurrent deployment phases can therefore occur. A deployment can report a state that never occurred twice in this codebase: bring every access to the lock keeping the lock away from any long-running race detector.
HXC-214	Bug	Queued	—	Four provider integrations each declare a lock that promises only to read, both modify their store to point to that same record rather than a copy that reads according to its name but writes in place. They assume it is safe, so the write happens under race conditions each other. And because the caller receives the value it does to the value it was given silently changes the result could reasonably expect. The result is that a process fails, or the reverse, and that an unrelated process fails without ever intending to touch it. The remedy is to fix this pattern: perform the update under the lock and add a test with a test that fails if the returned value is even.
HXC-215	Bug	Queued	—	The gate that checks whether each recent commit is consistent on two separate runs, naming a different commit for each. A commit builds cleanly when the gate's own commit is consistent. Packages it reported as broken were unrelated to the gate, which was the first clue. The gate has no time to act on the moment they happened rather than a run.

ATM ID	Type	Status	Severity	Description
				gate's own execution from a reproduction is the same. In a fresh throwaway checkout, all of them should be the same. The reproduction builds one. That points at interference rather than at any defect in the code being judged. It is not yet proven and should not be assumed. This may be the answer suggests, because the gate blocks release. It teaches people to dismiss it, and the day it is right. The habit will let the breakage through. The work is not done every time it is given the same input, and to produce an unchanged tree.
