We confirme rather than merely shipping the library: an au own sandbox code to the affected functions. Th

ATM ID	Type	Status	Severity	Description
				sandbox escaping onto the machine that hosts it exists to prevent. What remains unknown, and can actually influence those copy operations in sandbox feature is switched on in real deployment, a written decision backed by evidence: either a concrete, unreachable in our configuration, or a concrete feature, constraining the copy paths, or isolating them. No upgrade can close these, a deliberate decision. A complete copy of somebody else's web application it alone accounts for one hundred and thirty-nine dependency security warnings, including three that can be built or run: the startup configuration point in that folder, and its supporting packages have not been built two opposite ways at once. Because it is not built the way we actually run today, which is why they rank high in references it, the setup is broken and misleading. The recipe file, all one hundred and thirty-nine warnings, to whoever does it. Anyone reading our security report is a distortion, since it currently buries the small number of warnings. The expected outcome is an explicit decision, not a reference to properly maintain and build it, or remove it and replace it with a reference to the upstream hosted service. Before we get approval, the decision must be put to the operator. A small companion service we wrote ourselves as part of the standard deployment, and it carries a number of supporting packages, two of them rated high. Under the dependency warnings, these have no mitigating evidence in the code, unshipped, because it demonstrably ships, and it is not clear whether the affected functionality is ever exercised. place in the whole review where something was mentioned, which makes it far more deserving of attention than the other three is not really an upgrade problem at all: it is a feature switched off unless explicitly enabled, so updating the service protection on would leave the exposure in place. The current deployment running this service benefit. The evidence for the assessment of the three warnings, the two strategies for the protective setting explicitly verified as enabled, the service and the service rebuilt and confirmed working. The cache that remembers model information is not built, where its clock was never configured. That falls under the only way to build the cache always configured, but it is unexercised. On its own that is harmless. The

				if someone later edits it: a plausible-looking change to the current time would make every cached entry a lie in the past that the freshness check reads as a failure at expiry limit. Every entry would then be considered invalid and keep serving outdated model information indefinitely. The choice is to either add a small test that pins the time to a branch entirely and document that there is one, or to accept the risk. When a caller presents an API key, the server does a simple ordinary text comparison. That kind of comparison is not one that does not match, so a key sharing the first few characters is more reject than one that differs immediately. An attacker could exploit differences across many attempts can recover the key by guessing it outright. Network timing noise makes this attack is low rather than urgent, but it is a genuine weakness. A cheap: use the comparison function designed for this purpose, amount of time regardless of where the difference is introduced by recent work.
HXC-178	Bug	Queued	Low	
HXC-179	Task	Queued	Medium	The check that decides which websites may open connections deliberately allows requests that carry no origin information, because only browsers send that information and it legitimately omit it. It is safe today only because we prevent away anyone without valid credentials. The two checks nothing records or enforces that coupling: if someone bypasses the login check while working on something unrelated, the information would become completely ungated. The current work here is to add a check that specifically covers the connection upgrade, so the dependency is removed.
HXC-180	Task	Queued	Low	Three commits in the current release range do not refer to a piece of data that was not added in the first of those three points gets a build error. The tip of the branch corrected shortly afterwards. This cannot be rectified without rewriting published history, which the project policy is for anyone hunting a regression by stepping through the three points that fail to build for a reason unrelated to the may wrongly conclude the fault lies there. The current work affected points and their shared cause somewhat. The so the failure is recognised immediately as known and fixed from scratch.
HXC-181	Task	Queued	Medium	HXC-160 corrected the 21 stale references to scripts/generate_fixed_summary.sh across the repository. It added the CM-SUPERSEDED-GENERATOR-NAMES file. The sets were deliberately left untouched and are to be updated.

ATM ID	Type	Status	Severity	Description
				Constitution.md still carries 14 references across universal rules that projects other than HelixCode records such as the Phase 5 Go-binary-shim plan. This is a governance amendment that CONST-049 reconfigured upstream, then re-cascaded and postponed a session that closed HXC-160, and a canon amendment that drifted than the stale wording, so the canon was not updated. 45 owned submodules carry cascaded restatement of the correction applied in the parent repo is deliberate, because the fix names a HelixCode-specific mechanism of wording into decoupled, project-agnostic submodules that do not them and violate CONST-051(B). The correct solution is to use neutral canonical wording that names the work as a change and push it in the constitution submodule per the project's fleet and bump pointers. Who benefits: every contributor to the anchor text, and any agent reading a submodule's summaries are produced. Acceptance: canon rewording, the change is pushed to every constitution submodule and are re-cascaded, submodule pointers are bumped, and SUPERSEDED-GENERATOR-NAMING both pass. Every shipped change must carry recorded proof of the change by looking for the change's identifier inside the project's automatically stamp in whatever the project's change were recorded. That stamp is an identifier of evidence file written while the project happened. If, by coincidence, be accepted as that change's proof, it is completely unrelated. This has not yet happened. The change made while the project sat at a position that rewording is available to every recording the shared tooling. The project accept only identifiers deliberately declared as a position stamp. This needs care because the project's acceptance from evidence already recorded, so the project's quiet correction. The main handbook that tells contributors and contributors organised lists several folders at the top level to the project when only one is present, and refers to a top-level folder. Anyone following it — a new contributor, or a contributor's orientation — will look for things that are not broken or that they have checked out the wrong folder of the document, which is otherwise the author's. The correction is small and purely descriptive. The project's section to match, then keep the two in step as the project's
HXC-186	Bug	Queued	Medium	
HXC-188	Task	Queued	Low	

ATM ID	Type	Status	Severity	Description
HXC-189	Task	Queued	Low	One of the external projects this codebase depends on for its configuration still refers to it by its previous name. The hosting service silently forwards requests from the old name, so forwarding is a courtesy, not a guarantee: it depends on the project under the old name, and it is not honored. This is a dependency. If it stops working, fetching the project's name nobody recognises, which is unusually common. The project's current canonical name so the reference is on a redirect continuing to exist.
HXC-190	Bug	Queued	Low	When a running command is cut short because of a timeout, it says it was not a timeout. The check that sets the timer is the caller's own deadline, which usually has not been reached, so the command stopped the command. Investigation showed that the timer was either, because the internal signal it would come from was cancelled and never a timeout, and the timer was not a mechanism entirely. The effect is that anyone who uses the timer fails and no indication that a time limit was reached. The timer is in the wrong place. A sibling code path that runs correctly by doing it inside the timer's own callback.
HXC-191	Bug	Queued	Low	When a command is cancelled or times out, the timer is not reset, but anything it started, by signalling the whole command, works if the command was placed into its own sandbox enabled — the normal configuration — the sandbox switched off, the grouping step is skipped. The operating system to signal a group that does not work, an error is discarded. The result is a cancelled command that is dormant, because the only configuration that could have been so shipped path reaches it. It is worth fixing this, but it would appear only in an unusual configuration, so it is to diagnose later.
HXC-192	Bug	Queued	Low	Output from a running command is read line by line, and the line may be. When a line exceeds that limit the command is permanently for that stream, because the buffer is full and past it. Nothing else takes over the reading. The command is not until the operating system's own small buffer is full, and someone to read. So one unusually long line, which is readable output produce quite naturally, can be a problem. It is to keep draining and discarding the remainder of the line, abandoning the stream, so the producing command can continue.
HXC-193	Bug	Queued	High	

ATM ID	Type	Status	Severity	Description
				One of the small services we ship in a container address on a specific port to confirm the service is healthy. The service reads no configuration that is supposed to tell it which port to listen on, so it listens on the port the container publishes. And because the check queries an address where nothing can be unhealthy no matter how well the service is actually, replacing unhealthy containers will do so endlessly. This is unrelated security advisories in the same service, but nobody had exercised the health check since it was added. One of our own small services builds its web service that ships with the library it is based on. In doing so, it at all may make requests to it, and it never checks if the site visited by someone on the same machine could be the same and read its responses. This is the same weakness as the library's own toolkit, but because we handle the case of upgrading the library would not fix ours — the two are problems that merely look alike. That distinction is important, would make the warning disappear while leaving the original the origin of incoming requests against a list of known bad sites. The container definition for one of our services specifies which network port to use. The service never reads that value does nothing at all. The result is a security hole in the container definition where anyone would be able to effect — so a person adjusting it to move the service to a different port and would have no way to tell why. This also could be a health check were both written to match that in the service actually does. Either the service should be removed and the real behaviour documented, or it's the worst of the three options. The handbook that describes this project's technology includes one of its networking libraries. Both parts of the handbook because a security fix required moving off the old one, but deliberate; it is the handbook that is now wrong. A new contributor or an automated helper reading the handbook will confidently state a version that has not been found in the same document has already been found described in the handbook. Additional inaccuracy makes the whole document unreliable, recorded version to what is actually in use, and the handbook, for reason, so nobody later reverts it believing the handbook is correct. One test directory contains a duplicate of its own files. The files appear twice in the project at two different locations.

HXC-195	Bug	Queued	Medium	
HXC-196	Task	Queued	Medium	
HXC-197	Bug	Queued	Low	

ATM ID	Type	Status	Severity	Description
				renaming exercise that moved a tree while leaving the new one. Nothing reads the nested copy, so anyone searching the project finds two results which is real, and any tool that scans for duplicates blocks a useful check from being switched on: duplicates cannot be enabled while this one exists every run. Removing it requires first confirming the nested copy is genuinely the leftover and not the new one.
HXC-198	Bug	Queued	High	A serious defect was recently fixed where running a process behind would hang forever and permanently fill execution slots. A second function in the very same progress while they run, has the identical defect: readers to finish before waiting for the command to reach the path, so the same background process holds it. When the commands in the background reaches this function, this is the sixth time in one working cycle that it does not to its sibling a few lines away, which suggests that what else in the same file shares the pattern. The fix is a door, so this is a matter of applying it rather than the fix. A recent change gave one part of the project a new identity. The code could stop claiming the same identity. A corner case problem still exists searches for the old name and the new one contains the old one as a prefix — so the check for the new one as unfixed even though it is fixed. Anyone re-running the already done, and might undo the fix believing the new one also still describes the old arrangement in three parts of the whole name rather than a fragment, and to fix it what the code actually does now.
HXC-199	Bug	Queued	Medium	
HXC-200	Bug	Queued	Low	A detector was written to catch a specific kind of error: stuck trying to hand off a result nobody is collecting. In one particular description of what the worker does, it is in form of the same stall — where the worker waits for a result rather than a single handoff — and the detector was demonstrated rather than theorised: a deliberate test went completely undetected while the detector was active. What it does catch is the historical one, so the guard is not in the newer structure while breaking its escape route. Recognising both descriptions is a small change and a good defect rather than half of it.
HXC-201	Bug	Queued	High	The command the project's manuals give for running the tool is put them where it says. It builds the tool from the source file path relative to the project root, but the build system

ATM ID	Type	Status	Severity	Description
				the output lands inside the tool's own folder in destinations and reports success, leaving the r stale, and it creates empty placeholder files in version of the same command that was outrigl is now worse: a visible error became a silent o previously found in that folder and attributed give an absolute output path, or to make the to regardless of where it was built, and then to up currently enforces the broken form.
